

س

1.1 STARTING MATLAB, MATLAB WINDOWS

It is assumed that the software is installed on the computer, and that the user can start the program. Once the program starts, the MATLAB desktop window opens (Figure 1-1). The window contains four smaller windows: the Command Window, the Current Folder Window, the Workspace Window, and the Command History Window. This is the default view that shows four of the various windows of MATLAB. A list of several windows and their purpose is given in Table 1-1. The **Start** button on the lower left side can be used to access MATLAB tools and features.

Four of the windows—the Command Window, the Figure Window, the Editor Window, and the Help Window—are used extensively throughout the book and are briefly described on the following pages. More detailed descriptions are included in the chapters where they are used. The Command History Window, Current Folder Window, and the Workspace Window are described in Sections 1.2, 1.8.4, and 4.1, respectively.

Command Window: The Command Window is MATLAB's main window and opens when MATLAB is started. It is convenient to have the Command Window as the only visible window, and this can be done by either closing all the other windows (click on the x at the top right-hand side of the window you want to close) or by first selecting the **Desktop Layout** in the **Desktop** menu, and then

When typed, these words appear in blue. An error message is displayed if the user tries to use a keyword as a variable name. (The keywords can be displayed by typing the command iskeyword.)

A number of frequently used variables are already defined when MATLAB is started. Some of the predefined variables are:

- ans A variable that has the value of the last expression that was not assigned to a specific variable (see Tutorial 1-1). If the user does not assign the value of an expression to a variable, MATLAB automatically stores the result in ans.
- pi The number π .
- eps The smallest difference between two numbers. Equal to 2^(-52), which is approximately 2.2204e-016.
- inf Used for infinity.
- i Defined as $\sqrt{-1}$, which is: 0 + 1.0000i.
- j Same as i.
- NaN Stands for Not-a-Number. Used when MATLAB cannot determine a valid numeric value. Example: 0/0.

The predefined variables can be redefined to have any other value. The variables pi, eps, and inf, are usually not redefined since they are frequently used in many applications. Other predefined variables, such as i and j, are sometime redefined (commonly in association with loops) when complex numbers are not involved in the application.

1.7 USEFUL COMMANDS FOR MANAGING VARIABLES

The following are commands that can be used to eliminate variables or to obtain information about variables that have been created. When these commands are typed in the Command Window and the **Enter** key is pressed, either they provide information, or they perform a task as specified below.

Command	Outcome
clear	Removes all variables from the memory.
clear x y z	Removes only variables x , y , and z from the memory.
who	Displays a list of the variables currently in the memory.
whos	Displays a list of the variables currently in the memory and their sizes together with information about their bytes and class (see Section 4.1).

A variable that already exists can be reassigned a new value. For example:

```
>> ABB=72;
A value of 72 is assigned to the variable ABB.

>> ABB=9;
A new value of 9 is assigned to the variable ABB.

The current value of the variable is displayed when the name of the variable is typed and the Enter key is pressed.
```

Once a variable is defined it can be used as an argument in functions. For example:

```
>> x=0.75;

>> E=sin(x)^2+cos(x)^2

E =

1

>>
```

1.6.2 Rules About Variable Names

A variable can be named according to the following rules:

- Must begin with a letter.
- Can be up to 63 characters long.
- · Can contain letters, digits, and the underscore character.
- Cannot contain punctuation characters (e.g., period, comma, semicolon).
- MATLAB is case sensitive: it distinguishes between uppercase and lowercase letters. For example, AA, Aa, aA, and aa are the names of four different variables.
- No spaces are allowed between characters (use the underscore where a space is desired).
- Avoid using the name of a built-in function for a variable (i.e., avoid using cos, sin, exp, sqrt, etc.). Once a function name is used to define a variable, the function cannot be used.

1.6.3 Predefined Variables and Keywords

There are 20 words, called keywords, that are reserved by MATLAB for various purposes and cannot be used as variable names. These words are:

break case catch classdef continue else elseif end for function global if otherwise parfor persistent return spmd switch try while The last statement (x = 3x - 12) illustrates the difference between the assignment operator and the equal sign. If in this statement the = sign meant equal, the value of x would be 6 (solving the equation for x).

The use of previously defined variables to define a new variable is demonstrated next.

```
>> a=12

a =

12

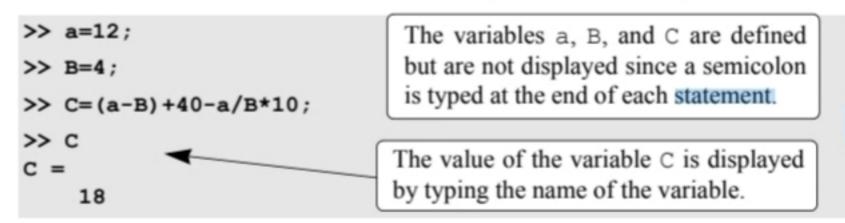

>> B=4

Assign 4 to B.

Assign 4 to B.
```

- If a semicolon is typed at the end of the command, then when the Enter key is pressed, MATLAB does not display the variable with its assigned value (the variable still exists and is stored in memory).
- If a variable already exists, typing the variable's name and pressing the Enter key
 will display the variable and its value in the next two lines.

As an example, the last demonstration is repeated below using semicolons.

Several assignments can be typed in the same line. The assignments must be separated with a comma (spaces can be added after the comma). When the Enter key is pressed, the assignments are executed from left to right and the variables and their assignments are displayed. A variable is not displayed if a semicolon is typed instead of a comma. For example, the assignments of the variables a, B, and C above can all be done in the same line.

```
>> a=12, B=4; C=(a-B)+40-a/B*10

a =

12

The variable B is not displayed because a semicolon is typed at the end of the assignment.
```

Table 1-5: Rounding functions (Continued)

Function	Description	Example
sign(x)	Signum function. Returns 1 if $x > 0$, -1 if $x < 0$, and 0 if $x = 0$.	>> sign(5) ans = 1

1.6 DEFINING SCALAR VARIABLES

A variable is a name made of a letter or a combination of several letters (and digits) that is assigned a numerical value. Once a variable is assigned a numerical value, it can be used in mathematical expressions, in functions, and in any MAT-LAB statements and commands. A variable is actually a name of a memory location. When a new variable is defined, MATLAB allocates an appropriate memory space where the variable's assignment is stored. When the variable is used the stored data is used. If the variable is assigned a new value the content of the memory location is replaced. (In Chapter 1 we consider only variables that are assigned numerical values that are scalars. Assigning and addressing variables that are arrays is discussed in Chapter 2.)

1.6.1 The Assignment Operator

In MATLAB the = sign is called the assignment operator. The assignment operator assigns a value to a variable.

Variable_name = A numerical value, or a computable expression

The left-hand side of the assignment operator can include only one variable name.
 The right-hand side can be a number, or a computable expression that can include numbers and/or variables that were previously assigned numerical values. When the Enter key is pressed the numerical value of the right-hand side is assigned to the variable, and MATLAB displays the variable and its assigned value in the next two lines.

The following shows how the assignment operator works.

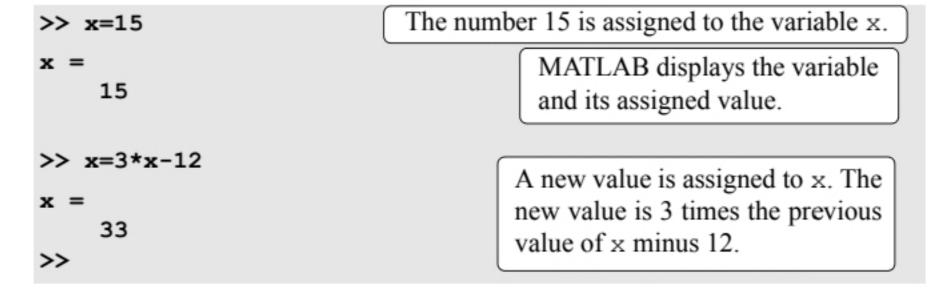

Table 1-3: Elementary math functions (Continued)

Function	Description	Example
factorial(x)	The factorial function x! (x must be a positive integer.)	>> factorial(5) ans = 120

Table 1-4: Trigonometric math functions

Function	Description	Example
sin(x) sind(x)	Sine of angle x (x in radians). Sine of angle x (x in degrees).	>> sin(pi/6) ans = 0.5000
cos(x) cosd(x)	Cosine of angle x (x in radians). Cosine of angle x (x in degrees).	>> cosd(30) ans = 0.8660
tan(x) tand(x)	Tangent of angle x (x in radians). Tangent of angle x (x in degrees).	>> tan(pi/6) ans = 0.5774
cot(x) cotd(x)	Cotangent of angle x (x in radians). Cotangent of angle x (x in degrees).	>> cotd(30) ans = 1.7321

The inverse trigonometric functions are asin(x), acos(x), atan(x), acot(x) for the angle in radians; and asind(x), acosd(x), atand(x), acotd(x) for the angle in degrees. The hyperbolic trigonometric functions are sinh(x), cosh(x), tanh(x), and coth(x). Table 1-4 uses pi, which is equal to π (see Section 1.6.3).

Table 1-5: Rounding functions

Function	Description	Example
round(x)	Round to the nearest integer.	>> round(17/5) ans = 3
fix(x)	Round toward zero.	>> fix(13/5) ans = 2
ceil(x)	Round toward infinity.	>> ceil(11/5) ans = 3
floor(x)	Round toward minus infinity.	>> floor(-9/4) ans = -3
rem(x,y)	Returns the remainder after x is divided by y.	>> rem(13,5) ans = 3

of using the function sqrt(x) when MATLAB is used as a calculator with scalars.

Tutorial 1-2: Using the sqrt built-in function.

```
Argument is a number.
>> sqrt(64)
ans =
      8
>> sqrt(50+14*3)
                                      Argument is an expression.
ans =
     9.5917
                                    Argument includes a function.
>> sqrt(54+9*sqrt(100))
ans =
     12
>> (15+600/4)/sqrt(121)
                                   Function is included in an expression.
ans =
     15
>>
```

Some commonly used elementary MATLAB mathematical built-in functions are given in Tables 1-3 through 1-5. A complete list of functions organized by category can be found in the Help Window.

Table 1-3: Elementary math functions

Function	Description	Example
sqrt(x)	Square root.	>> sqrt(81) ans = 9
nthroot(x,n)	Real <i>n</i> th root of a real number <i>x</i> . (If <i>x</i> is negative <i>n</i> must be an odd integer.)	>> nthroot(80,5) ans = 2.4022
exp(x)	Exponential (e^x) .	>> exp(5) ans = 148.4132
abs(x)	Absolute value.	>> abs(-24) ans = 24
log(x)	Natural logarithm. Base <i>e</i> logarithm (ln).	>> log(1000) ans = 6.9078
log10(x)	Base 10 logarithm.	>> log10(1000) ans = 3.0000

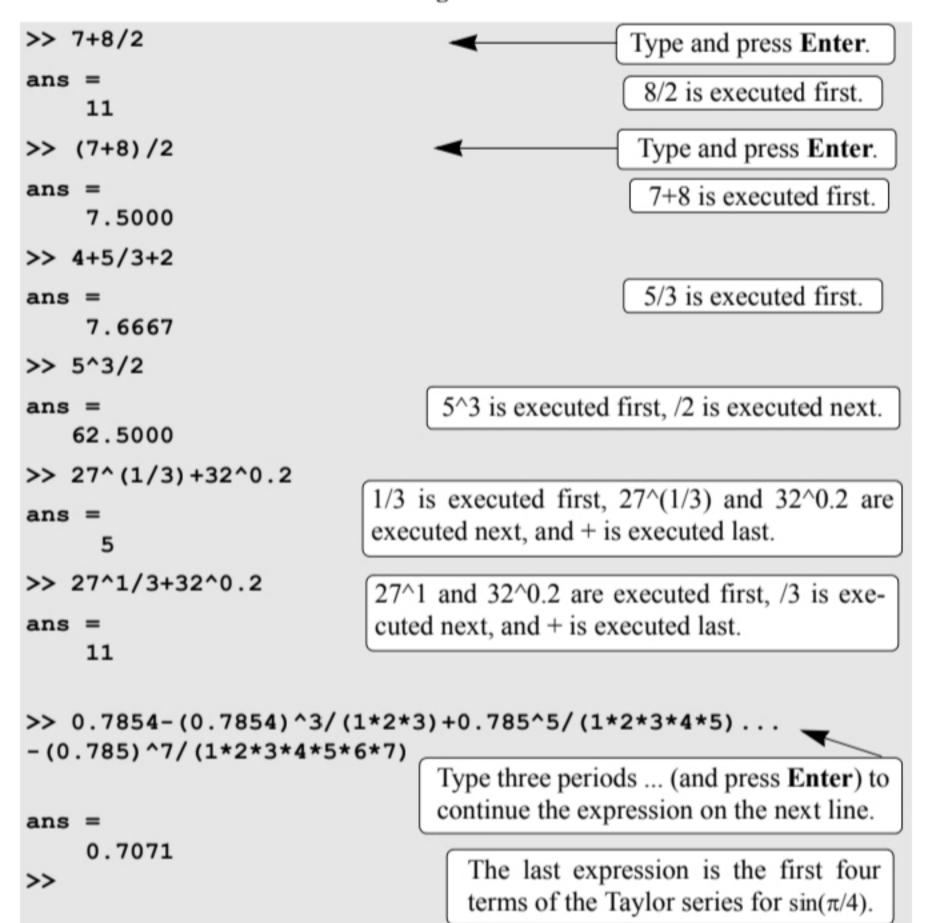

Table 1-2: Display formats

Table 1-2. Display formats		
Command	Description	Example
format short	Fixed-point with 4 decimal digits for: 0.001 ≤ number ≤ 1000 Otherwise display format short e.	>> 290/7 ans = 41.4286
format long	Fixed-point with 15 decimal digits for: 0.001 ≤ number ≤ 100 Otherwise display format long e.	>> 290/7 ans = 41.428571428571431
format short e	Scientific notation with 4 decimal digits.	>> 290/7 ans = 4.1429e+001
format long e	Scientific notation with 15 decimal digits.	>> 290/7 ans = 4.142857142857143e+001
format short g	Best of 5-digit fixed or floating point.	>> 290/7 ans = 41.429
format long g	Best of 15-digit fixed or floating point.	>> 290/7 ans = 41.4285714285714
format bank	Two decimal digits.	>> 290/7 ans = 41.43
format compact	Eliminates empty lines to allow more lines with information displayed on the screen.	
format loose	Adds empty lines (opposite of compact).	

1.5 ELEMENTARY MATH BUILT-IN FUNCTIONS

In addition to basic arithmetic operations, expressions in MATLAB can include functions. MATLAB has a very large library of built-in functions. A function has a name and an argument in parentheses. For example, the function that calculates the square root of a number is sqrt(x). Its name is sqrt, and the argument is x. When the function is used, the argument can be a number, a variable that has been assigned a numerical value (explained in Section 1.6), or a computable expression that can be made up of numbers and/or variables. Functions can also be included in arguments, as well as in expressions. Tutorial 1-2 shows examples

Tutorial 1-1: Using MATLAB as a calculator.

1.4 DISPLAY FORMATS

The user can control the format in which MATLAB displays output on the screen. In Tutorial 1-1, the output format is fixed-point with four decimal digits (called short), which is the default format for numerical values. The format can be changed with the format command. Once the format command is entered, all the output that follows is displayed in the specified format. Several of the available formats are listed and described in Table 1-2.

MATLAB has several other formats for displaying numbers. Details of these formats can be obtained by typing help format in the Command Window. The format in which numbers are displayed does not affect how MATLAB computes and saves numbers.

tions are:

Operation	Symbol	Example
Addition	+	5 + 3
Subtraction	_	5 – 3
Multiplication	*	5 * 3
Right division	/	5/3
Left division	\	$5 \setminus 3 = 3 / 5$
Exponentiation	^	$5 ^3 (means 5^3 = 125)$

It should be pointed out here that all the symbols except the left division are the same as in most calculators. For scalars, the left division is the inverse of the right division. The left division, however, is mostly used for operations with arrays, which are discussed in Chapter 3.

1.3.1 Order of Precedence

MATLAB executes the calculations according to the order of precedence displayed below. This order is the same as used in most calculators.

<u>Precedence</u>	Mathematical Operation
First	Parentheses. For nested parentheses, the innermost are executed first.
Second	Exponentiation.
Third	Multiplication, division (equal precedence).
Fourth	Addition and subtraction.

In an expression that has several operations, higher-precedence operations ar executed before lower-precedence operations. If two or more operations have th same precedence, the expression is executed from left to right. As illustrated in th next section, parentheses can be used to change the order of calculations.

1.3.2 Using MATLAB as a Calculator

The simplest way to use MATLAB is as a calculator. This is done in the Command Window by typing a mathematical expression and pressing the **Enter** key MATLAB calculates the expression and responds by displaying ans = and the numerical result of the expression in the next line. This is demonstrated in Tutoria 1-1.

The semicolon (;):

When a command is typed in the Command Window and the **Enter** key is pressed, the command is executed. Any output that the command generates is displayed in the Command Window. If a semicolon (;) is typed at the end of a command the output of the command is not displayed. Typing a semicolon is useful when the result is obvious or known, or when the output is very large.

If several commands are typed in the same line, the output from any of the commands will not be displayed if a semicolon is typed between the commands instead of a comma.

Typing %:

When the symbol % (percent) is typed at the beginning of a line, the line is designated as a comment. This means that when the **Enter** key is pressed the line is not executed. The % character followed by text (comment) can also be typed after a command (in the same line). This has no effect on the execution of the command.

Usually there is no need for comments in the Command Window. Comments, however, are frequently used in a program to add descriptions or to explain the program (see Chapters 4 and 6).

The clc command:

The clc command (type clc and press **Enter**) clears the Command Window. After working in the Command Window for a while, the display may become very long. Once the clc command is executed a clear window is displayed. The command does not change anything that was done before. For example, if some variables were defined previously (see Section 1.6), they still exist and can be used. The up-arrow key can also be used to recall commands that were typed before.

The Command History Window:

The Command History Window lists the commands that have been entered in the Command Window. This includes commands from previous sessions. A command in the Command History Window can be used again in the Command Window. By double-clicking on the command, the command is reentered in the Command Window and executed. It is also possible to drag the command to the Command Window, make changes if needed, and then execute it. The list in the Command History Window can be cleared by selecting the lines to be deleted and then selecting **Delete Selection** from the **Edit** menu (or right-click the mouse when the lines are selected and then choose **Delete Selection** in the menu that opens).

1.3 ARITHMETIC OPERATIONS WITH SCALARS

In this chapter we discuss only arithmetic operations with scalars, which are numbers. As will be explained later in the chapter, numbers can be used in arithmetic calculations directly (as with a calculator) or they can be assigned to variables, which can subsequently be used in calculations. The symbols of arithmetic opera-

1.2 Working in the Command Window

The Command Window is MATLAB's main window and can be used for executing commands, opening other windows, running programs written by the user, and managing the software. An example of the Command Window, with several simple commands that will be explained later in this chapter, is shown in Figure 1-5.

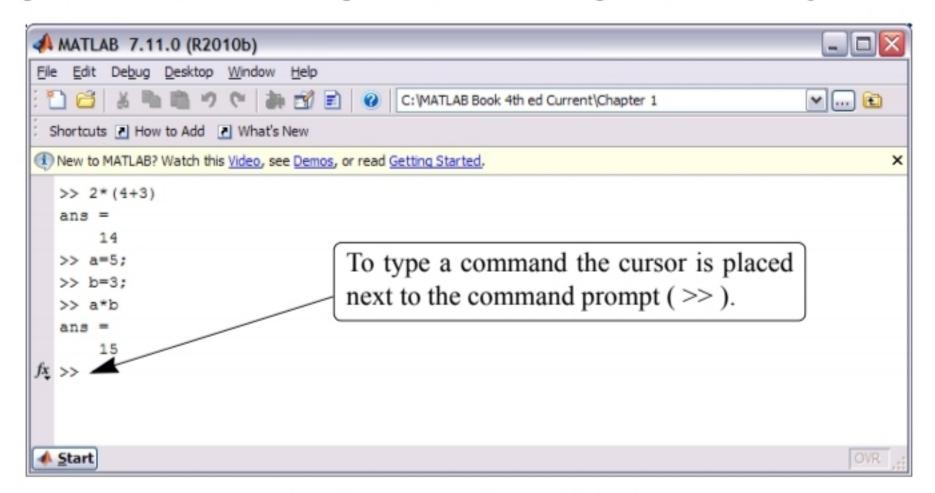

Figure 1-5: The Command Window.

Notes for working in the Command Window:

- To type a command the cursor must be placed next to the command prompt (>>).
- Once a command is typed and the Enter key is pressed, the command is executed.
 However, only the last command is executed. Everything executed previously
 (that might be still displayed) is unchanged.
- Several commands can be typed in the same line. This is done by typing a comma
 between the commands. When the Enter key is pressed the commands are executed in order from left to right.
- It is not possible to go back to a previous line that is displayed in the Command Window, make a correction, and then re-execute the command.
- A previously typed command can be recalled to the command prompt with the uparrow key (↑). When the command is displayed at the command prompt, it can be modified if needed and then executed. The down-arrow key (↓) can be used to move down the list of previously typed commands.
- If a command is too long to fit in one line, it can be continued to the next line by typing three periods ... (called an ellipsis) and pressing the Enter key. The continuation of the command is then typed in the new line. The command can continue line after line up to a total of 4,096 characters.

Figure 1-4: The Help Window.

When MATLAB is started for the first time the screen looks like that shown in Figure 1-1. For most beginners it is probably more convenient to close all the windows except the Command Window. (Each of the windows can be closed by clicking on the button.) The closed windows can be reopened by selecting them from the **Desktop** menu. The windows shown in Figure 1-1 can be displayed by selecting first **Desktop Layout** in the **Desktop** menu and then **Default** from the submenu. The various windows in Figure 1-1 are docked to the desktop. A window can be undocked (become a separate, independent window) by clicking on the button on the upper right-hand corner. An independent window can be redocked by clicking on the button.

U

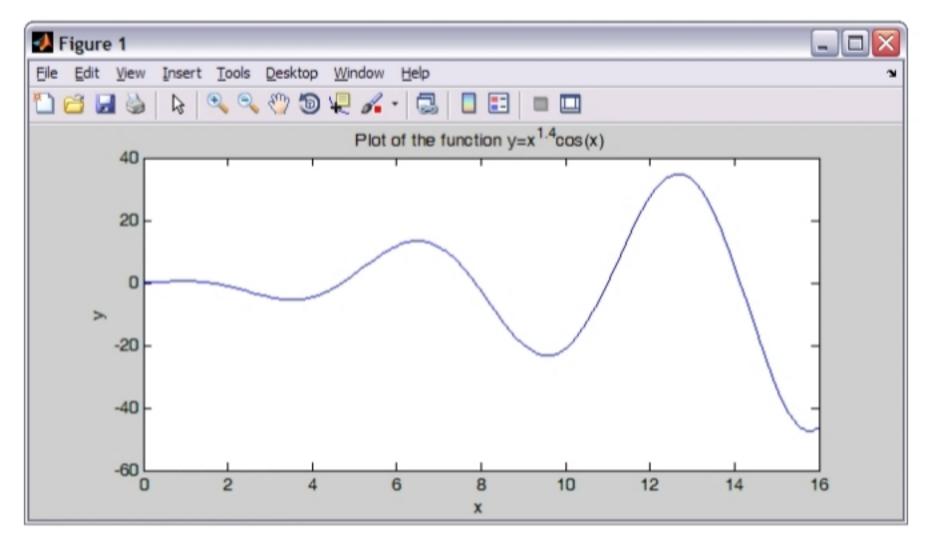

Figure 1-2: Example of a Figure Window.

Editor Window: The Editor Window is used for writing and editing programs. This window is opened from the **File** menu. An example of an Editor Window is shown in Figure 1-3. More details on the Editor Window are given in Section 1.8.2, where it is used for writing script files, and in Chapter 7, where it is used to write function files.

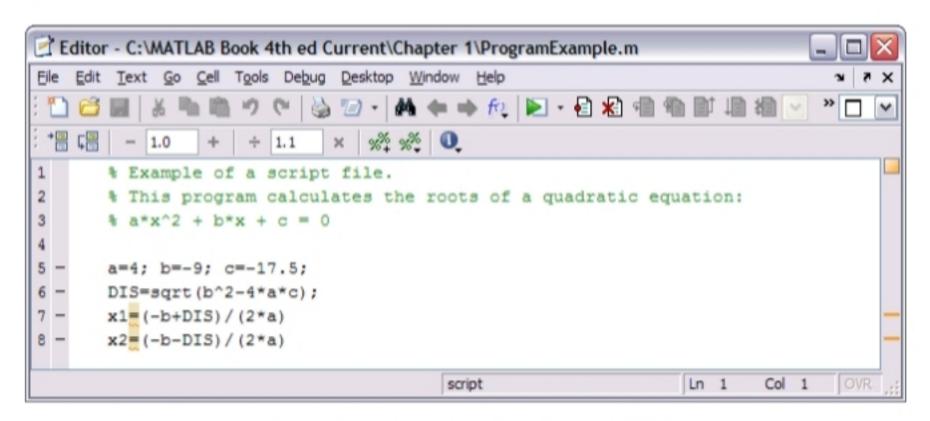

Figure 1-3: Example of an Editor Window.

Help Window: The Help Window contains help information. This window can be opened from the **Help** menu in the toolbar of any MATLAB window. The Help Window is interactive and can be used to obtain information on any feature of MATLAB. Figure 1-4 shows an open Help Window.

selecting **Command Window Only** from the submenu that opens. Working in the Command Window is described in detail in Section 1.2.

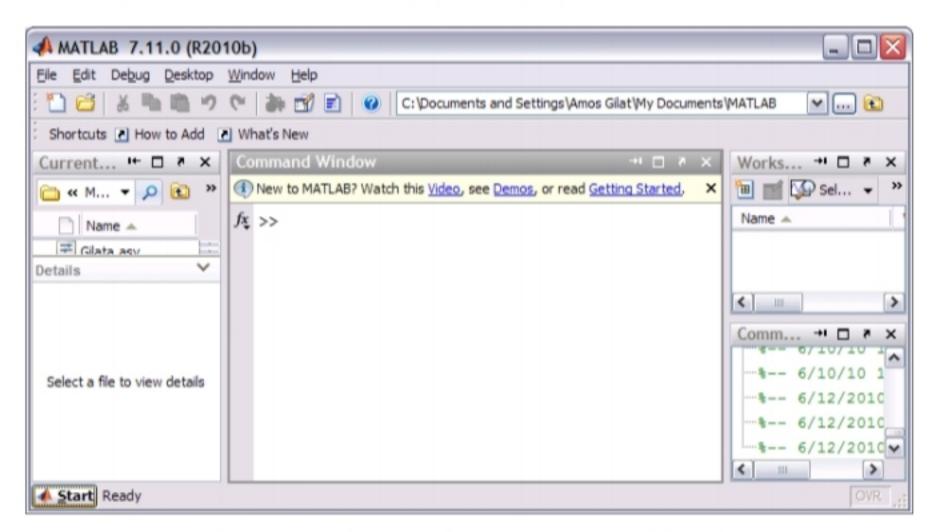

Figure 1-1: The default view of MATLAB desktop.

Table 1-1: MATLAB windows

Window	Purpose
Command Window	Main window, enters variables, runs programs.
Figure Window	Contains output from graphic commands.
Editor Window	Creates and debugs script and function files.
Help Window	Provides help information.
Command History Window	Logs commands entered in the Command Window.
Workspace Window	Provides information about the variables that are used.
Current Folder Window	Shows the files in the current folder.

Figure Window: The Figure Window opens automatically when graphics commands are executed, and contains graphs created by these commands. An example of a Figure Window is shown in Figure 1-2. A more detailed description of this window is given in Chapter 5.
